

Zluri

Problem statement: Pitch a basic module of Employee dashboard which can solve for employee use cases

Background: Zluri Dashboard's Users are only Admins of the company like CEO/CTO/COO/IT Admin/Finance Admin/HR Admin since Zluri enables visibility of the whole organisation. But a use case of serving a product to Employees of the organisations remains untouched. This led Zluri to launch its own standalone product to serve the employees and named it the "Employee Dashboard".

Why build an employee dashboard now?

*Zluri's mission is to **Accelerate the world's transition to SaaS**. Its current offering serves a limited portion of IT employees and hence, there is a gap to be filled that Zluri can look to fill using its core competencies and features of its existing product.*

My approach:

Objective

Since this is a new offering by the company, the objective should be to promote and ensure maximum reach and subsequent adoption of this product

Employee Personas

A typical IT company will have the following departments: Dev, QA, DevOps, HR, Finance, UX/UI designers, Product. Each department may have their own tools and Software that each member uses to accomplish their daily tasks.

Raj (Software Developer, Company X)

- Android developer; started career in company X (product-based) right after college; has been working here for 2 years
- Used a different IDE to write code in college. Had to shift to a different one which is the standard platform used in his team.
- Had started coding in Java 16; over 2 years Java was renewed twice (present: version 18) with multiple new features introduced. Only got to know about it through a friend who switched jobs to a startup which was using the latest version.
- Apart from project related responsibilities, Raj uses the company ERP to access his employment related information
- He uses the IT portal to raise tickets regarding any hardware/software issues or requests

Swati (QA Team lead, Company Y)

- Has been in QA for 6 years, leads a team of 8 QAs in Company Y (service-based) for a US-based client
- Needs to know if there are new tools in the market that could make her team's work efficient and reduce the go-to-market time
- Needs to get licensed software for use by her team in the shortest amount of time possible

Since our **objective is maximum reach for the new employee dashboard**, we need to target the **team member persona (since they are maximum in number)** and hence, we will identify and solve for their problems

Pain points

Here are some identified pain points for the team members persona:

	Pain points	Frequency	Intensity	Urgency to be solved	Details
	Adjusting to new platforms, when joining a new team	2	6	12	There is a need for systematic Knowledge Transfer for new people in the team
	Awareness of new software/new versions of existing software	5	6	30	Employees need to be aware of software/tools that can increase their efficiency. They also need to know whether the time and effort in setting up and getting used to the new software will yield an appropriate increase in efficiency/output
	Getting licensed version of new software	4	7	28	Once they decide to switch to a new software, they need to get a licensed version of the same for all team members at the earliest possible
	Follow up/update on active tickets on different platforms	6	4	24	There could be different active issues on different platforms (e.g: IT portal, employee helpdesk) and the user might not be timely responding timely to all of them, leading to lower overall efficiency

Through the above analysis, we see that the **urgency to be solved (Frequency * Intensity)** is maximum for the problem 'awareness of new software'. Hence our employee dashboard will require this problem to be solved first.

Solution

Jobs to be done:

When I want use the best software to do my job efficiently, **but** don't have knowledge about all available software in the market, **help me** in knowing about and choosing the appropriate software, **so that** I do not have to spend my time and effort in doing so

	Feature	Details	Impact	Effort	Efficiency of feature
	App discovery	Employees can be made aware of software being used in their organisation or even outside (for similar work)	10	3	3.3
	App stats	Feature for the user to look at appropriate utilization metrics for the current software used, so they can compare the benefits and costs of replacing the software	6	2	3.0
	App demo	Demos of the new software, so that user can get a hands-on experience and judge their comfort	9	6	1.5
	App categorization	All employee applications will be categorized for ease to access and better UX. These categories could be project specific apps (used in specific teams), generic apps (used across organisation). Further categorization could be made according to utility of app (e.g.: Design, coding, testing, etc.)	5	2	2.5

Effort scores have been given keeping in mind that features that already exist in the flagship offering need to be built from scratch again and can be reused in the employee dashboard

Based on **Efficiency (Impact/Effort)** scores, App discovery, App stats and App categorization are the features that I would prioritize in my employee dashboard

Mockups

Employee profile setup

This will help to create cohorts of users in terms of department, organization or designation

Each employee will setup their employee dashboard by defining these fields which will be editable only through approval of relevant authorities

The mockup shows a web interface for an 'Employee Dashboard'. On the left is a sidebar with three links: 'Discover', 'My apps', and 'Profile', with 'Profile' being the active link. The main content area is titled 'Employee Dashboard'. It contains four form fields: 'Company' (text input with 'ABC'), 'Name' (text input with 'Ameya Sinha'), 'Department' (dropdown menu with 'Quality Assurance' selected, showing options 'Development' and 'Product'), and 'Designation' (dropdown menu with 'Software Engineer' selected, showing options 'Team lead' and 'Manager'). A blue 'Submit' button is at the bottom.

App categorization

Once Zluri's algorithms identify the software/tools used by the employee, categories will be created as follows:

- Most used apps will be identified according to timeshare of total active time
- App category (defined as metadata by app providers) will be used as a filter to display specific cohorts of applications used by the employee

The mockup shows the 'Employee Dashboard' with the 'My apps' link active in the sidebar. It displays a greeting 'Good evening Ameya!'. Below this is a section titled 'Most used:' with an arrow pointing to a row of four app cards. Each card shows an app icon, name, timeshare percentage, and last used date. Below this is a section titled 'Design apps:' with an arrow pointing to a row of three app cards. To the right of these cards is a 'Display app category:' dropdown menu with 'Design' selected, showing options 'Development', 'Testing', and 'Project management tools'.

App	Timeshare	Last used
App 1	24%	Today
App 2	18%	Today
App 3	15%	Today
App 4	8%	Today

App discovery

Using the employee profile data of users in various organizations (shared voluntarily by organisations), cohorts can be created and displayed on the basis of designation and departments

- This will help employees generate awareness about what tools/apps are used in the industry for specific roles and departments. These can be categorized by utility
- The employees can choose to browse through/search apps used in their organization/outside as well as apps used in projects that they are a part of

App stats

Employees can browse through apps in all categories.

- They have the option to save apps that they would want to refer to later or get the licenses for.
- They can compare the apps with the ones they have on their system in terms of multiple criteria.
- Machine learning algorithms can suggest better alternatives for the user by performing cost-benefit analysis using the available data

Go-To-Market

Pre launch

Objective: *Ensure product-market fit (PMF) with the chosen target group*

- **Train internal teams** (e.g.: customer support on the new offering)
- **Establish metrics (see below)** that would be under surveillance to signal smooth onboarding and engagement of users. Track the metrics for **estimated vs actual values**
- **Launch a beta release** for a chosen cohort of users. **UX and in-app behaviour can be tracked** using tools like heatmaps.
- **Monitor user feedback and reported bugs** and inculcate it before the final launch of the product
- **Conduct PMF surveys**

During launch

Objective: *Ensure smooth launch, feature discovery, and engagement of feature at scale*

- **Promotion:** Current users of Zluri can be pitched demos of employee dashboard or allowed free usage for limited time period
- The identified target groups should be made aware of the new feature through about the use cases of the new feature
- A run-through of the steps should be provided in the form of videos to make the onboarding simpler
- Features to be **A-B tested can be tested at scale** and feedback collected
- The **engagement metrics should be specially paid attention to**

Post launch

Objective: *Continuous feedback from app usage through established channels. Agile deployment of improvements and bug fixes*

- PMF surveys on larger groups
- **NPS scores** to be measured and evaluated
- The **retention and health metrics should be paid attention to** as the product begins to scale and reach critical mass
- Reported bugs should be fixed in **shorter sprint cycles till a stable version exists in the market**
- Adequate customer support should be available

North star metric: Number of licenses purchased for employee dashboard

Category	Metric	Comments
Adoption	# of employee signups	To note if employees are successfully signing up for the dashboard
Engagement	Avg. time spent per user on app discovery, % of app runs through dashboard	To understand if the employees are completing the intended actions
Retention	Churn rate, % change in users (Week-on-week)	To note the drop-off/addition of users
Health	Correct app cohorts created, new apps added to correct cohorts	To check whether algorithms are functioning as expected

Future scope

- Creating flow for employees to apply for software licenses through dashboard after user discovers a new software that they would like to use. This will also require creating a chain of command on the backend so that approvals for acquiring new licenses can reach the relevant chain of command (**High impact, Medium effort**)
- Creating a built-in platform for users to demo new software and establish their comfort before deciding to switch to it (**High impact, High effort**)
- Options for users to set favourite apps on the My apps (categorization page) (**Medium impact, Low effort**)

Pitfalls

Pitfalls	Mitigation
Organization might not condone visibility of applications at all levels	There can be a feature for the admin to restrict visibility of apps to within the organisation or within the project team only
App stats feature might not generate accurate recommendations in the beginning	Using large sets of data to train the algorithms to make better recommendations

Summary

For the *objective of ensuring maximum reach of a new employee offering* of Zluri SaaS management platform, we target the *team member persona's* problem of *lack of awareness of new software in the market* and solve it by creating an **employee dashboard** that would include features of app discovery in the employee system and comparison to other apps in the market on the basis of designated app stats. Employee will also be able to access a categorized view of their apps for better UX
